## *AIM*

---

The aim of this workshop is to evaluate your centre pivot irrigation system. To do this you need to determine the rate that water is being applied, and how uniformly that water is being distributed over your irrigation area. To check these you need to know the mean application (MA) and distribution uniformity (DU) for your system. These worksheets outline the equipment and procedure needed for you to complete these tasks.

## *SYSTEM OVERVIEW*

---

A centre pivot is a travelling irrigation line that pivots at one end and rotates in a circle. It is made up of towers (commonly 4 to 12) that support the irrigation pipe and spray outlets. They have a pair of wheels at the junction of each tower that is driven by electric motors or hydraulic motors (oil or water). The speed of the pivot system is usually set on the outside wheels with the other drive points engaging when they get behind or a valve is adjusted with the angle of that joint.

The size of the sprinkler outlets increases as you move away from the centre, as the outer sections of the pivot are covering a larger area than the centre sections. This means that the longer a pivot is, the greater the application rate needed at the end.

A major advantage of centre pivots is that they can operate at quite low pressures, thus reducing pumping cost. If the site is undulating, pressure regulators are fitted to each sprinkler outlet to equalise the output at varying heights. Most modern centre pivots operate at only 100 kPa. With pipes from the centre to the pump site, the total pressure required can be as low as 300 kPa.

Some centre pivots have end guns fitted to increase the area irrigated. The application pattern and rate of end guns is often very different to the rest of the irrigator, creating uneven watering. End guns often require a booster pump to increase the operating pressure.

## EQUIPMENT NEEDED

---

### *To measure sprinkler coverage:*

- Catch cans
- Weights to prevent catch cans blowing away
- A shovel to smooth catch can area, and where necessary for partially burying the cans
- A measuring cylinder or jug with graduations in millilitres
- A 30-metre measuring tape; and possibly a short rule
- A calculator, a pen and evaluation sheets
- Manufacturer's sprinkler performance charts

### *To measure pressure:*

- An accurate pressure gauge with an appropriate scale so it works mid-range at your normal pressures (say 0 to 400 kPa) to 1000 kPa
- A Pitot tube attachment (pronounced pit-oh) (Figure 1), or a threaded 15 mm PVC tee and fittings such as reducing bushes for small low-level sprinklers, or a Schrader valve, or a needle valve fitting (Figure 2)

Figure 1: Pitot Tube

Figure 2: Schrader Valve

## *EVALUATION METHOD*

---

To assess the performance of your centre pivot system, you need to measure the pressure and flow at various points in the system, the operating speed at the far end, and the output of the sprinklers using catch cans. From these you will be able to calculate the application and uniformity. To do this, work through the following procedure.

### **Occupational Health and Safety**

Whilst working with your centre pivot irrigator you, and anyone assisting you, should at all times be aware of the inherent dangers associated with working near moving machinery. Safety should be the primary concern at all times.

1. Fill out the first sections of the centre pivot data sheet with details about the crop, soils and the centre pivot. You will need to measure the length of each span and the distance to the last wheel track (where the travel speed will be measured).

### ***Speed measurement***

Note that the pivot must be moving (at its normal speed) throughout the test, otherwise the difference in flow rates between the inboard and outboard sprinklers will give you incorrect results. If all is correct, the depths in all of the catch cans will be similar.

2. Measure the pivot's speed by staking out a measured distance (10 m) around the outer wheel track and recording the time required for the end drive unit to travel between the stakes. Record the time and distance on the data sheet.

### ***Water output measurement***

3. Place the catch cans at intervals no greater than 6 m to cover the whole wetted length of the pivot.

4. Measure the width of the wetting pattern near the end drive unit and record this.
5. After the system has passed all catch cans, and no more water is landing in them, measure the volumes in the catch cans and record these on the catch can sheet. (For long pivots, the catch cans under the first one or two spans need not be recorded, as the time to pass over them is too great. There will be little effect on the calculations. However, the catch can positions under these spans *must* be noted and the catch volume recorded as an 'X'.)

### ***Measuring pressure and flow***

6. Measure and record the pressure and flow at outlets near the start and end of the pivot and also at other positions on towers along the pivot.

### ***Calculating the results***

7. After taking all measurements, complete the calculations. As the calculations for a centre pivot are quite complex, it is best to put the figures into a computer spreadsheet and let the computer work out the results. Your trainer should have the appropriate program. If you are doing the evaluation at home, ask for a copy of the program or get your local irrigation adviser to assist you. The program may be available to download from the WaterWise web pages on NSW Agriculture's web site.
8. Record the results in the application results table. For those who wish to avoid the use of the computer, you may use a calculator. The procedure is fully detailed in these notes.
9. Rank the volumes starting with the lowest amount, (1<sup>st</sup>, 2<sup>nd</sup> 3<sup>rd</sup>, and so forth). Do this for about one third of the cans
10. Calculate the “weighted catch” by multiplying the volume collected in the catch can by the number of that catch can. Follow the steps in your field record sheet
11. Calculate the Average Application per Pass of your system using the Table given. Record the results in the Application Results table
12. Calculate the Distribution Uniformity (DU) of your system using the DU Table. Record the results in the Application Results table

## Data Sheet Example

Data sheet	Date
Name	<i>Rotundo Douse</i>
Crop	<i>Lucerne</i>
Location/block	<i>Paddock 2/3</i>
Soil texture of Block	<i>Sandy loam over sand</i>
Effective root depth	<i>1.0 metres</i>
Rootzone RAW	<i>48 mm</i>
Irrigator make	<i>Lindsay Zimmatic</i>
Emitter model	<i>Nelson R3000 Rotators</i>
Number of Spans	<i>6</i>
Number of emitters along span	<i>20</i>
Total length of spans (Pivot length)	<i>324 metres</i>
Wetted width (end span)	<i>8 M</i>
Length of overhang	<i>25 metres</i>
Sprinklers on overhang	<i>8 sprinklers</i>
End gun present	Yes <b>No</b>
End gun radius	<i>0</i>
Pressure Compensated	Yes <b>No</b>
Specified operating pressure at pivot	<i>175 kPa</i>
Specified flow rate	<i>53.0 L/s 0.19 ML/hr</i>
Irrigation frequency	<i>2 - 4 days</i>
Wind direction and speed during test (Table 1)	<i>LIGHT BREEZE</i>
Catch Can Diameter	<i>113 MM</i>
Time to travel test distance	<i>12 MINUTES 9 SECONDS</i>
Distance travelled	<i>10 METRES</i>

### *Irrigation System Calculations*

<b>Determine the wetted radius of the pivot</b>		
<b>Wetted radius = pivot length + length of overhang + end gun reach</b>		
<b>Pivot length (distance to outside track)</b>	324 metres	<b>A</b>
<b>Length of overhang</b>	25 metres	<b>B</b>
<b>End gun reach</b>	No end gun = 0 metres	<b>C</b>
<b>Wetted radius</b>	<b>A + B + C</b>	
	324 + 25 + 0 = 349 metres	<b>D</b>
<b>Determine the area that is wet by the pivot</b>		
<b>Wetted area = <math>\Pi</math> (Pi) x (wetted radius)<sup>2</sup> ÷ 10 000 *</b>		
<b><math>\Pi</math> (Pi)</b>	3.14	<b>Pi</b>
<b>* ÷ by 10 000 to convert into hectares</b>	= Pi x D <sup>2</sup> ÷ 10 000 = 3.14 x 349 <sup>2</sup> ÷ 10 000 = 3.14 x 121801 ÷ 10 000 = 38.2 ha	<b>WA</b>

<b>Estimate the speed of the Pivot</b>		
<b>Distance Travelled</b>	<b>10 metres</b>	<b>E</b>
<b>Time for distance travelled</b>	<b>12 MINUTES 9 SECONDS</b>	
<b>Time in seconds</b>	<b>729 seconds</b>	<b>F</b>
<b>Travel Speed = Distance travelled ÷ Time (seconds) x 3600</b>		
<i>*multiply by 3600 to convert the speed into metres per Hour</i>	$E \div F \times 3600^*$ $10 \div 729 \times 3600$ $= 49.4 \text{ metres per hour}$	<b>G</b>
<b>Estimate how large your irrigation circle is</b>		
<b>Circumference (Outside wheel track) = 6.28* x pivot radius</b>		
<b>* Circumference of a circle</b> <b>= 2 x pi x radius of circle</b> <b>2 x pi = 6.28</b>	$6.28 \times A$ $6.28 \times 324$ $= 2035 \text{ metres}$	<b>H</b>
<b>Calculate the time for one revolution (complete circle) of the pivot</b>		
<b>Time for one revolution = Circumference ÷ Travel speed</b>		
	$H \div G$ $2035 \div 49.4$ $= 41.2 \text{ hours}$	<b>K</b>

### Field Record Sheet (example)

If you have access to the computer program, you only need to fill in columns A and B of this table. The computer will do the rest.

<b>Property location:</b>		<i>Roundabout</i>			<b>Date</b>	<i>16th Aug 2000</i>

12	50	463	8750	68212
13				
14				
15				
16				
17				
18				
19				
20				
21				
22				

$$\begin{aligned}
 \text{LQ limit} &= \text{TN} \div 4 \\
 &= 1666 \div 4 \\
 &= 416.5
 \end{aligned}$$

413 is the closest cumulative catch can number.

Therefore we take catch can number 14 with the Low quarter weighted catch of 59462

$$\text{LQWC} = 59462$$

*Calculating the Average Application and Instantaneous Application Rate*

<b>Calculate the average amount of water being applied with each pass</b>			
<b>Average Application</b>	<b>= Total of weighted catch can</b>	<b>÷ Total sum of catch can Numbers</b>	<b>÷ Conversion factor</b>
<b>Total Sum of catch can Numbers</b> Add up the numbers in Column A where water was collected in the can. Ignore empty can numbers.	<b>1666</b>	<b>TN</b>	
<b>Total of all weighted catches</b> Add up the numbers in column D.	<b>325328</b>	<b>TC</b>	
<b>Conversion Factor (Table 2)</b> Our catch cans for this example were 113 mm in diameter	<b>10.0</b>	<b>CF</b>	
<b>Average Application per pass</b>	<b>=</b>	<b>TC ÷ TN ÷ CF</b>	
		<b>325328 ÷ 1666 ÷ 10.0</b> <b>= 19.5 mm</b>	<b>AA</b>
Transfer the AA figure to the Application Results Table (earlier).			
<b>Calculate the amount of water being applied each hour</b>			
Wetted diameter	<b>8 metres</b>	<b>WD</b>	
<b>Instantaneous Application Rate at outer tower</b> <b>= Average Application x Travel speed ÷ wetted width</b>			
		<b>AA x G ÷ WD</b> <b>19.5 x 49.4 ÷ 8</b> <b>= 120.4 mm / hour</b>	<b>IAR</b>

IAR should be compared to the infiltration rate of your soil. If the IAR at the outer end of centre pivot is much greater than the infiltration rate, runoff will occur. Methods of reducing this problem should be investigated eg. Installing outlets with a larger wetted diameter, increasing soil organic matter, using soil conditioners, etc.

## *Conversion from Volume into depth*

**Table 2 Converting mL to mm**

In order to convert Volume into depth (millimetres) we need to use a conversion factor. The conversion factors are listed in Table 2. You select your conversion factor by measuring the diameter of the mouth of your catch can

For instance, if the diameter of your catch can is 110 mm then our conversion factor from Table 2 will be 9.5 (circled).

If our cans collected 674 mL, then the conversion is our volume divided by the conversion factor;

$$674 \text{ mL} \div 9.5 = 71 \text{ mm}$$

Therefore, the depth of water applied during the example test was 71 mm

Diameter of catch can (mm)	Figure to divide the collected amount by
75	4.4
80	5.0
90	6.4
100	7.9
102	8.2
104	8.5
106	8.8
108	9.2
110	9.5
112	9.9
113	10.0
114	10.2
115	10.4
120	11.3
125	12.25
145	16.5
165	21.3
200	31.4
220	38.0

If you use 4 litre square plastic ‘ice cream’ containers, 1 litre collected in one of these is equivalent to 25 mm of irrigation. On a calculator, use

**water collected in mL” ÷ 40 = ..... mm**

## ***Calculating the Distribution Uniformity***

- Step 1** Determine the lowest quarter limit (LQ limit)
  
- Step 2** Use the Lowest Quarter Catch table to add up the figures in column C of your Field record sheet, starting at the lowest volume rank (1<sup>st</sup>).
  
- Step 3** Continue to add the weighted catch until the total exceeds the figure for LQ limit. Subtract the last figure, so the total is less than LQ limit.
  
- Step 4** The figures you have added are your LQ catches- shade or highlight them on your Field record sheet
  
- Step 5** Follow the steps in the Distribution Uniformity Table
  
- Step 6** Record your results in the Application Results Table

*Distribution Uniformity*

<b>Calculate the number of Lowest Quarter of catch cans (LQ Limit)</b>		
<b>Lowest quarter Limit</b>	<b>= TN ÷ 4</b>	
	<b>= 1666 ÷ 4</b>	<b>LQ Limit</b>
	<b>= 416.5</b>	
<b>Add up the Depth of water caught in the Lowest Quarter Cans (LQ Depth)</b>		
<b>Lowest quarter Depth</b>	<b>= Total Lowest quarter weighted volumes ÷ Total lowest quarter can positions ÷ conversion factor</b>	
From the LQ Table, find the Cumulative (or Total) Catch Can Position Number closest to LQ Limit.	<b>= 413</b>	<b>TNLQ</b>
From the LQ Table, find Cumulative (or Total) Weighted Catch for TNLQ	<b>= 59462</b>	<b>LQWC</b>
<b>Lowest quarter depth</b>	<b>= LQWC ÷ TNLQ ÷ CF</b>	
	<b>= 59462 ÷ 413 ÷ 10</b>	<b>LQ depth</b>
	<b>= 14.4 mm</b>	
<b>Calculate the Distribution Uniformity of the Pivot</b>		
<b>Distribution Uniformity = LQ Depth ÷ AA</b>		
	<b>= 14.4 ÷ 19.5</b>	
	<b>= 0.74</b>	<b>DU</b>
Convert into a percentage by multiplying by 100	<b>DU x 100</b>	
	<b>= 0.74 x 100</b>	
	<b>= 74 %</b>	
Transfer the DU figure to the Application Results Table		

### *Application results*

<b>Calculate the expected application per pass of the pivot</b>		
<b>Specified Flow Rate</b>		<b>0.19 ML/h</b>
<b>Hour per revolution</b>	<b>K</b>	<b>41.2 Hours</b>
<b>Wetted Area</b>	<b>WA</b>	<b>38.2 Ha</b>
<p><b>Nominal Average Application per pass:</b></p> $= \frac{\text{Specified flow rate (ML/hr)} \times \text{Hours per revolution}}{\text{Wetted Area (ha)}} \times 100$ $= \frac{0.19 \times 41.2}{38.2} \times 100$ $= 20.5 \text{ mm}$		
<b>Compare the expected application per pass to the Measured application per pass</b>		
<p><b>Measured Average Application per pass:</b> From computer program OR your own calculations using procedure at end of these notes.</p>	<b>AA</b>	<b>19.5 .mm</b>
<p>If the Measured Average Application per pass is greatly different from the Nominal Average Application per pass, something is significantly wrong.</p>		
<p>The measured application per pass should be compared to the rootzone RAW on the data sheet. For the example, the application depth is one quarter of the RAW.</p>		
<b>Estimate the distribution Uniformity of the pivot</b>		
<p><b>Lower quarter output per pass</b>  From computer program OR your own calculations using procedure in these notes.</p>	<b>LQ Depth</b>	<b>14.4 mm</b>
<p><b>Distribution uniformity</b>  From computer program OR your own calculations using procedure in these notes.</p>	<b>DU</b>	<b>74 %</b>

Distribution uniformity above 75% is quite acceptable for field crops. If the DU is too low, this means that at least 25% of the area being irrigated is receiving less water than the rest.

## How long to irrigate

Using the AAR value and the RAW value for the crop on this soil, you may estimate how long you need to irrigate to ensure adequate wetting from this sprinkler.

To estimate how long to irrigate to fill the RAW you need to compare the Average application per pass with the RAW. You will also need to take into account the DU.

<b>Calculate the best amount of water to apply each pass of the pivot</b>		
<b>Average application per pass</b>	= 19.5 mm	<b>AA</b>
<b>DU calculated</b>	= 0.74 (74%)	<b>DU</b>
<b>Ideal application per pass to compensate for the DU</b>	$\text{AA} \div \text{DU}$ $19.5 \div 0.74$ = 26 mm	<b>N</b>
<b>Calculate how much of the Rootzone RAW is applied with each pass</b>		
<b>RAW for this crop from Centre pivot data sheet.</b>	= 48 mm	<b>RAW</b>
<b>Percentage of RAW applied per pass</b>	$= \text{AA} \div \text{RAW} \times 100$ $= 19.5 \div 48 \times 100$ = 41 %	<b>P</b>
<b>Calculate pivot speed required to apply the full rootzone RAW</b>		
<b>Travel speed required to apply the full RAW on each pass of the Pivot</b>	$\text{Percentage RAW} \times \text{Travel Speed} \times \text{DU\%}$	
	$P \times G \times \text{DU\%}$ $0.41 \times 49.4 \times 74\% (0.74)$ = 15 m/hr	<b>R</b>
<b>Calculate time of one revolution to applying the rootzone RAW</b>		
<b>Time for one revolution at this speed = Circumference ÷ Travel speed</b>		
	$H \div R$ $2035 \div 15$ = 135.6 hours. or 5.6 days	

***Flow Record Sheet (example)***

	<b>Nozzle type</b>	<b>Time for 10L Seconds</b>	<b>Flow measured L/s</b>	<b>Flow as per system design L/s</b>	<b>Flow difference C - D</b>	<b>Flow variation <math>E \div D \times 100</math></b>
	<b>A</b>	<b>B</b>	<b>C</b>	<b>D</b>	<b>E</b>	<b>F</b>
<b>Span 1, last sprinkler</b>	<b>#15 15/128</b>	<b>71.4</b>	<b>0.14</b>	<b>0.13</b>	<b>0.01</b>	<b>+7.7%</b>

<b>Span 4, last sprinkler</b>	<b>138 kPa</b>	<b>112 kPa</b>	<b>+26 kPa</b>	<b>+23.2 %</b>
<b>Span 5, last sprinkler</b>	<b>115 kPa</b>	<b>107 kPa</b>	<b>+8 kPa</b>	<b>+7.5 %</b>
<b>Span 6, last sprinkler</b>	<b>102 kPa</b>	<b>105 kPa</b>	<b>-3 kPa</b>	<b>-2.9 %</b>

### ***What do the pressure and flow readings tell us?***

You have collected a series of figures on your record sheet. Using these figures, you can calculate the variations for the system. Too great a variation indicates that the system is not operating most effectively. Pressure variation may be 'above' or 'below' the desired figure. A negative (minus) figure indicates variation below the specification.

A variation of more than  $\pm 10\%$  is unacceptable and indicates that there may be some problems with your irrigation set up or design.

(Note: if pressure compensators are used in your system, then all the sprinkler pressures should be almost the same.)

If both pressure and flow are above specification, the pump is probably giving a flow rate greater than specified. If pressure is below specification and flow is above specification in many outlets, the outlets are probably bigger than

specified, perhaps through wear or being replaced with wrong sized outlets. If pressure is above and flow is lower, there is a blockage somewhere, most likely in the outlets. If pressure and flow are below specification, there is a restriction in the main line before the pivot or the pump is giving a flow rate lower than specified.

**The following sheets are provided to complete the activities presented at the workshop and for use on your own centre pivot**

## *EVALUATION SHEETS*

<b>Data sheet</b>	<b>Date</b>
<b>Name</b>	
<b>Crop</b>	
<b>Location/block</b>	
<b>Soil texture of Block</b>	
<b>Effective root depth</b>	<b>metres</b>
<b>Rootzone RAW</b>	<b>mm</b>
<b>Irrigator make</b>	
<b>Emitter model</b>	
<b>Number of Spans</b>	
<b>Number of emitters along span</b>	
<b>Total length of spans (Pivot length)</b>	<b>metres</b>
<b>Wetted width (end span)</b>	<b>m</b>
<b>Length of overhang</b>	<b>metres</b>
<b>Sprinklers on overhang</b>	<b>sprinklers</b>
<b>End gun present</b>	<b>Yes          No</b>
<b>End gun radius</b>	
<b>Pressure Compensated</b>	<b>Yes          No</b>
<b>Specified operating pressure at pivot</b>	<b>kPa</b>
<b>Specified flow rate</b>	<b>L/s                  ML/hr</b>
<b>Irrigation frequency</b>	<b>days</b>
<b>Wind direction and speed during test (Table 1)</b>	
<b>Catch Can Diameter</b>	<b>mm</b>
<b>Time to travel test distance</b>	<b>minutes          seconds</b>
<b>Distance travelled</b>	<b>metres</b>

### *Irrigation System Calculations*

<b>Determine the wetted radius of the pivot</b>		
<b>Wetted radius = pivot length + length of overhang + end gun reach</b>		
<b>Pivot length</b> (distance to outside track)	..... metres	<b>A</b>
<b>Length of overhang</b>	..... metres	<b>B</b>
<b>End gun reach</b>	..... metres	<b>C</b>
<b>Wetted radius</b>	<b>A + B + C</b>	
	..... + ..... + .....  = ..... metres	<b>D</b>
<b>Determine the area that is wet by the pivot</b>		
<b>Wetted area = Pi x (wetted radius)<sup>2</sup> ÷ 10 000 *</b>		
<b>Pi</b>	<b>3.14</b>	<b>Pi</b>
<b>* ÷ by 10 000 to convert into hectares</b>	= Pi x D <sup>2</sup> ÷ 10 000  = 3.14 x ..... <sup>2</sup> ÷ 10 000  = ..... ha	<b>WA</b>

**Estimate the speed of the Pivot**

<b>Distance Travelled</b>	..... metres	<b>E</b>
---------------------------	--------------	----------

<b>Time for distance travelled</b>	..... minutes ..... seconds	
------------------------------------	-----------------------------	--

<b>Time in seconds</b>	..... seconds	<b>F</b>
------------------------	---------------	----------

**Travel Speed = Distance travelled ÷ Time (seconds) x 3600**

<i>*multiply by 3600 to convert the speed into metres per Hour</i>	$E \div F \times 3600^*$ $..... \div ..... \times 3600^*$ $= ..... \text{ metres per hour}$	<b>G</b>
--	---	----------

**Estimate how large your irrigation circle is**

**Circumference (Outside wheel track) = 6.28\* x pivot radius**

<p><b>* Circumference of a circle</b></p> <p>= 2 x pi x radius of circle</p> <p>2 x pi = 6.28</p>	$6.28 \times A$ $6.28 \times .....$ $= ..... \text{ metres}$	<b>H</b>

22				

$$\begin{aligned}
 \text{LQ limit} &= \text{TN} \div 4 \\
 &= \dots \div 4 \\
 &= \dots
 \end{aligned}$$

Closest cumulative catch can number .....

Therefore we take catch can number .....

with the Low quarter weighted catch of .....

$$\text{LQWC} = \dots$$

*Calculating the Average Application and Instantaneous Application Rate*

<b>Calculate the average amount of water being applied with each pass</b>			
<b>Average Application</b>	<b>= Total of weighted catch can</b>	<b>÷ Total sum of catch can Numbers</b>	<b>÷ Conversion factor</b>
<b>Total Sum of catch can Numbers</b> Add up the numbers in Column A where water was collected in the can. Ignore empty can numbers.	.....		<b>TN</b>
<b>Total of all weighted catches</b> Add up the numbers in column D.	.....		<b>TC</b>
<b>Conversion Factor (Table 2)</b> Our catch cans for this example were 113 mm in diameter	.....		<b>CF</b>
<b>Average Application per pass</b>	<b>=</b>	<b>TC ÷ TN ÷ CF</b>	
		..... ÷ ..... ÷ ..... = ..... mm	<b>AA</b>
Transfer the AA figure to the Application Results Table (earlier).			
<b>Calculate the amount of water being applied each hour</b>			
Wetted diameter	..... metres		<b>WD</b>
<b>Instantaneous Application Rate = Average Application x Travel speed ÷ wetted width</b>			
		<b>AA x G ÷ WD</b> ..... x ..... ÷ ..... = ..... mm/hour	<b>IAR</b>

IAR should be compared to the infiltration rate of your soil. If the IAR at the outer end of centre pivot is much greater than the infiltration rate, runoff will occur. Methods of reducing this problem should be investigated eg. Installing outlets with a larger wetted diameter, increasing soil organic matter, using soil conditioners, etc.

## Conversion from Volume into depth

**Table 2 Converting mL to mm**

In order to convert Volume into depth (millimetres) we need to use a conversion factor. The conversion factors are listed in Table 2. You select your conversion factor by measuring the diameter of the mouth of your catch can

For instance, if the diameter of your catch can is 110 mm then our conversion factor from Table 2 will be 9.5 (circled).

If our cans collected 674 mL, then the conversion is our volume divided by the conversion factor;

$$674 \text{ mL} \div 9.5 = 71 \text{ mm}$$

Therefore, the depth of water applied during the example test was 71 mm

Diameter of catch can (mm)	Figure to divide the collected amount by
75	4.4
80	5.0
90	6.4
100	7.9
102	8.2
104	8.5
106	8.8
108	9.2
110	9.5
112	9.9
113	10.0
114	10.2
115	10.4
120	11.3
125	12.25
145	16.5
165	21.3
200	31.4
220	38.0

If you use 4 litre square plastic 'ice cream' containers, 1 litre collected in one of these is equivalent to 25 mm of irrigation. On a calculator, use

$$\text{water collected in mL} \div 40 = \text{..... mm}$$

## ***Calculating the Distribution Uniformity***

- Step 1** Determine the lowest quarter limit (LQ limit)
- Step 2** Use the Lowest Quarter Catch table to add up the figures in column C of your Field record sheet, starting at the lowest volume rank (1<sup>st</sup>).
- Step 3** Continue to add the weighted catch until the total exceeds the figure for LQ limit. Subtract the last figure, so the total is less than LQ limit.
- Step 4** The figures you have added are your LQ catches- shade or highlight them on your Field record sheet
- Step 5** Follow the steps in the Distribution Uniformity Table
- Step 6** Record your results in the Application Results Table

*Distribution Uniformity*

<b>Calculate the number of Lowest Quarter of catch cans (LQ Limit)</b>		
<b>Lowest quarter Limit</b>	= TN ÷ 4	
	= ..... ÷ 4	<b>LQ Limit</b>
	= .....	
<b>Add up the Depth of water caught in the Lowest Quarter Cans (LQ Depth)</b>		
<b>Lowest quarter Depth</b>	= Total Lowest quarter weighted volumes ÷ Total lowest quarter can positions ÷ conversion factor	
From the LQ Table, find the Cumulative (or Total) Catch Can Position Number closest to LQ Limit.	.....	<b>TNLQ</b>
From the LQ Table, find Cumulative (or Total) Weighted Catch for TNLQ	.....	<b>LQWC</b>
<b>Lowest quarter depth</b>	= LQWC ÷ TNLQ ÷ CF	
	..... ÷ ..... ÷ .....	<b>LQ depth</b>
	= ..... mm	
<b>Calculate the Distribution Uniformity of the Pivot</b>		
<b>Distribution Uniformity = LQ Depth ÷ AA</b>		
	..... ÷ .....	<b>DU</b>
	= .....	
Convert into a percentage by multiplying by 100	<b>DU x 100</b>	
	= ..... x 100	
	= .....%	
Transfer the DU figure to the Application Results Table		

### *Application results*

<b>Calculate the expected application per pass of the pivot</b>		
<b>Specified Flow Rate</b>		<b>ML/h</b>
<b>Hour per revolution</b>	<b>K</b>	<b>Hours</b>
<b>Wetted Area</b>	<b>WA</b>	<b>Ha</b>
<p><b>Nominal Average Application per pass:</b></p> $= \frac{\text{Specified flow rate (ML/hr)} \times \text{Hours per revolution}}{\text{Wetted Area (ha)}} \times 100$ $= \dots \times \dots \div \dots \times 100$ $= \dots \text{ mm}$		
<b>Compare the expected application per pass to the Measured application per pass</b>		
<p><b>Measured Average Application per pass:</b> From computer program OR your own calculations using procedure at end of these notes.</p>	<b>AA</b>	..... <b>mm</b>
<p>If the Measured Average Application per pass is greatly different from the Nominal Average Application per pass, something is significantly wrong.</p>		
<p>The measured application per pass should be compared to the rootzone RAW on the data sheet. For the example, the application depth is one quarter of the RAW.</p>		
<b>Estimate the distribution Uniformity of the pivot</b>		
<p><b>Lower quarter output per pass</b></p> <p>From computer program OR your own calculations using procedure in these notes.</p>	<b>LQ Depth</b>	..... <b>mm</b>
<p><b>Distribution uniformity</b></p> <p>From computer program OR your own calculations using procedure in these notes.</p>	<b>DU</b>	..... <b>%</b>

Distribution uniformity above 75% is quite acceptable for field crops. If the DU is too low, this means that at least 25% of the area being irrigated is receiving less water than the rest.

## How long to irrigate

Using the AAR value and the RAW value for the crop on this soil, you may estimate how long you need to irrigate to ensure adequate wetting from this sprinkler. To estimate how long to irrigate to fill the RAW you need to compare the Average application per pass with the RAW. You will also need to take into account the DU.

<b>Calculate the best amount of water to apply each pass of the pivot</b>		
<b>Average application per pass</b>	..... mm	<b>AA</b>
<b>DU calculated</b>	..... %	<b>DU</b>
<b>Ideal application per pass to compensate for the DU</b>	$AA \div DU$ ..... $\div$ ..... = ..... mm	<b>N</b>
<b>Calculate how much of the Rootzone RAW is applied with each pass</b>		
<b>RAW for this crop from Centre pivot data sheet.</b>	..... mm	<b>RAW</b>
<b>Percentage of RAW applied per pass</b>	$= AA \div RAW \times 100$ $= ..... \div ..... \times 100$ $= ..... \%$	<b>P</b>
<b>Calculate pivot speed required to apply the full rootzone RAW</b>		
<b>Travel speed required to apply = Percentage RAW x Travel Speed x DU% the full RAW on each pass</b>		
	$P \times G \times DU$ ..... X ..... X ..... = ..... m/hr	<b>R</b>
<b>Calculate time of one revolution to applying the rootzone RAW</b>		
<b>Time for one revolution at this speed = Circumference <math>\div</math> Travel speed</b>		
	$H \div R$ $= ..... \div .....$ $= ..... \text{ hours or } ..... \text{ days}$	

***Flow Record Sheet***

	<b>Nozzle type</b>	<b>Time for 10L Seconds</b>	<b>Flow measured L/s</b>	<b>Flow as per system design L/s</b>	<b>Flow difference C - D</b>	<b>Flow variation <math>E \div D \times 100</math></b>
	<b>A</b>	<b>B</b>	<b>C</b>	<b>D</b>	<b>E</b>	<b>F</b>
<b>Span 1, last sprinkler</b>						
<b>Span 2, last sprinkler</b>						
<b>Span 3, last sprinkler</b>						
<b>Span 4, last sprinkler</b>						
<b>Span 5, last sprinkler</b>						
<b>Span 6, last sprinkler</b>						

### *Pressure Record Sheet*

	<b>Pressure measured</b>	<b>Pressure as per system design</b>	<b>Pressure difference A - B</b>	<b>Pressure Variation C ÷ B x 100</b>
	<b>A</b>	<b>B</b>	<b>C</b>	<b>D</b>
<b>At Pivot centre</b>				
<b>Span 1, last sprinkler</b>				
<b>Span 2, last sprinkler</b>				
<b>Span 3, last sprinkler</b>				
<b>Span 4, last sprinkler</b>				
<b>Span 5, last sprinkler</b>				
<b>Span 6, last sprinkler</b>				

### ***What do the pressure and flow readings tell us?***

You have collected a series of figures on your record sheet. Using these figures, you can calculate the variations for the system. Too great a variation indicates that the system is not operating most effectively. Pressure variation may be 'above' or 'below' the desired figure. A negative (minus) figure indicates variation below the specification. A variation of more than  $\pm 10\%$  is unacceptable and indicates that there may be some problems with your irrigation set up or design.

If both pressure and flow are above specification, the pump is probably giving a flow rate greater than specified. If pressure is below specification and flow is above specification in many outlets, the outlets are probably bigger than specified, perhaps through wear or being replaced with wrong sized outlets. If pressure is above and flow is lower, there is a blockage somewhere, most likely in the outlets. If pressure and flow are below specification, there is a restriction in the main line before the pivot or the pump is giving a flow rate lower than specified.
